INTRODUCTION

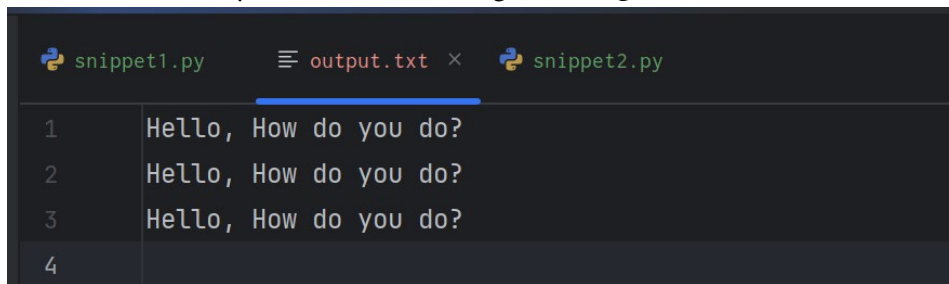

The purpose of this assignment was to debug two Python code snippets and ensure they run correctly. After fixing the errors, the first program successfully created and wrote to a file called output.txt, while the second program correctly calculated and printed the total value. This report explains what errors were found in each snippet and how they were fixed. Enjoy!

THE PROCESS

Snippet1

For the first code snippet, the program was intended to write a message into a text file. The error occurred because it attempted to combine a string with an incompatible data type. To correct this, the variable was simplified to contain only a string, ensuring proper concatenation. The program was also updated to close the file after writing to prevent file handling issues. After these changes, the code successfully writes the message to output.txt without errors

```
1 Hello, How do you do?
2 Hello, How do you do?
3 Hello, How do you do?
4
```

Snippet2

The second snippet contained several syntax errors, such as missing indentation, a missing colon, and incorrect use of the sum() function within a loop. To resolve this in the simplest and most effective way, the function was rewritten to directly calculate the sum of all values in the list and multiply the result by two. A sample function call was added to demonstrate that it works correctly. After these corrections, the code runs properly and displays the expected output.
